In this paper, a squeeze broad-band antenna based on the composite right-left handed transmission line (CRLH-TL) structure with enhancement gain is proposed and investigated. With CRLH metamaterial technology embedded, the proposed squeeze broad-band antenna is presented with best in bandwidth, size, efficiency and radiation patterns. To realize characteristics of the antenna, the printed I-shaped gaps into the rectangular radiation patches are used. This antenna is constructed of the four unit cells, also presented antenna is designed from 2.2 GHz to 3.05 GHz which corresponding to 32% bandwidth. The overall size of the presented antenna is  $22\text{mm} \times 7\text{mm} \times 0.8\text{mm}$  or  $0.16\lambda_0 \times 0.05\lambda_0 \times 0.006\lambda_0$  at the operating frequency  $f=2.2\text{GHz}$  (where  $\lambda_0$  is free space wavelength). The radiation peak gain and the maximum efficiency which occurs at 3.05GHz are 4.1dBi and 68.86%, respectively.

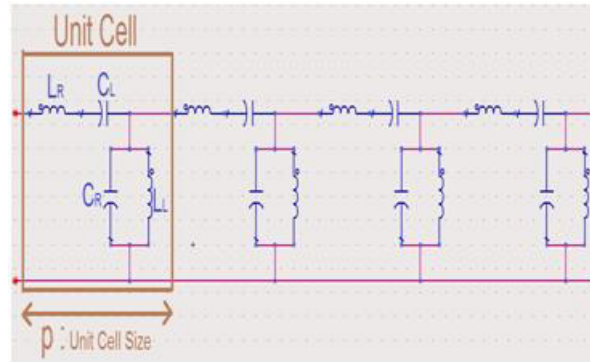

**Keywords:** Squeeze antenna, Broad-band antenna, Composite Right/Left-Handed Transmission Line (CRLH-TL), Metamaterial (MTM)

## INTRODUCTION

Microstrip patch antennas have found extensive application in wireless communication systems due to their low profile, low cost, relatively simple fabrication, compatibility with planar circuitry, planar structures, and unidirectional radiation capability. Antenna miniaturization is extremely important for modern wireless communication systems. The conventional approach for miniaturizing the antenna size is to print the radiator on a high dielectric substrate. However, because of the capacitive nature of the patch geometry and the existence of strong impedance contrast between the antenna substrate and the free space surrounding region, a large amount of electric energy is trapped inside the dielectric material resulting in a narrow antenna bandwidth and radiation loss. To overcome these problems we using of the MTM technology and the printed patch technique. These ways the antenna can

be miniaturized while the system bandwidth and radiation characteristics are automatically improved.

In recent years, metamaterials have been used for the patch antenna substrate to miniaturize it. Recently, novel antennas have been designed by using composite right/left-handed transmission line (CRLH-TL) metamaterials (Lai and Itoh, 2004; Herraiz Martínez et al., 2008). Unlike traditional right-handed (RH) transmission materials, metamaterials based on left-handed (LH) transmission lines (TLs) have unique features of anti-parallel group and phase velocities (Lai and Itoh, 2004; Herraiz-Martínez et al., 2008; Mao et al., 2005). Pure LH TLs cannot be implemented due to the existence of RH parasitic effects that occur naturally in practical LH TLs. CRLH-TL structures have been proposed, which also include RH effects. In this article, a squeeze broad-band patch antenna filled with CRLH

structures is proposed.

### CRLH-TL Theory

The concept of LHMs was first theorized by the Russian physicist (Veselago, 1968). Metamaterials (MTM) are artificial structures that can be designed to exhibit specific electromagnetic properties not commonly found in nature. Recently, MTM with simultaneously negative permittivity ( $\epsilon$ ) and permeability ( $\mu$ ), more commonly referred to as left-handed (LH) materials, have received substantial attention in the scientific and engineering communities. The unique properties of LHMs have allowed novel applications, concepts, and devices to be developed. LHMs are considered to be a more general model of composite right/left hand (CRLH) structures, which also include right-handed (RH) effects that occur naturally in practical LHMs. LHMs support electromagnetic waves with group and phase velocities that are anti-parallel, known as backward waves. Since resonant structures such as SRRs are lossy and narrow-banded, they are often difficult to implement for microwave applications. The general TL approach provides insight into the physical phenomena of LHMs and provides an efficient design tool for LH applications. The TL approach of LHMs, presented in this article, has led to nonresonant

structures with lower loss and wider bandwidth. In particular, MTM with RH and LH properties known as CRLH MTM have led to the development of several novel microwave devices.

As illustrated in figurev1 the composite right/left-handed (CRLH) transmission line (TL) (Caloz and Itoh, 2003) is a TL composed of the periodic repetition of a unit cell comprising a series inductance and a shunt capacitance as well as a series capacitance and a shunt inductance. The series capacitance and shunt inductance provide left-handedness (anti-parallel phase and group velocities) (Caloz and Itoh, 2003; Smith et al., 2000) at lower frequencies, whereas the series inductance and shunt capacitance provide the right-handedness (parallel phase and group velocities) at higher frequencies. The CRLH-TL is intrinsically non-resonant and thereby presents the advantages of lower loss and broader bandwidth than resonant-type left-handed (LH) materials (Smith et al., 2000). In addition, the CRLH TL appropriately represents real distributed LH structures (Caloz and Itoh, 2003), which have inevitable distributed parasitic series inductance and shunt capacitance, in contrast to the idealized LH TL which represents only a series capacitance and shunt inductance in the unit cell. The CRLH-TL can be implementing in the two cases, balance and unbalance cases, and there is the unique phenomenon of vanishment of the bandgap

**Figure 3.** Configuration of the presented squeeze broad-band patch antenna composed of the four unit cells based on CRLH MTM-TL. a) Top view, b) Isometric view.

between the LH and RH modes in the balanced CRLH TL. In the particular “balanced” case when the inductance and capacitance ratios of the LH and RH components of the unit cell are identical, that is,  $\frac{L_L}{C_L} = \frac{L_R}{C_R}$ , is satisfied, and the bandgap vanishes. It should be noted that at  $\beta = 0$  the wavelength is infinite ( $\lambda_g = \infty$ ) and the structure is perfectly homogeneous. In the balanced CRLH TL, we can have a seamless transition between the LH and RH ranges with infinite-wavelength wave with energy transmission ( $v_g \neq 0$ ). In contrast, when  $\left(\frac{L_L}{C_L} = \frac{L_R}{C_R}\right)$  is not satisfied (unbalanced case), the group velocities become zero, and there is therefore no propagation ( $v_g = 0$ ).

### Proposed antenna design procedure

In this paper, we employing printed planar technique for our antenna design, since printed planar structures are good nominee for antenna design because of their

advantages which include foot print area reduction, loss less and non-discrete values (Mohammad et al., 2012; Mohammad et al., 2012). A squeeze broad-band patch antenna with improvement gain based on CRLH-TL presented in here, which consists of four unit cells while each unit cell will be designed by two rectangular radiation patches with printed I-shaped gaps into patches, and the spiral inductor accompanying metallic via connected to the ground plane. Figure 2 display equivalent circuit model of each cell as CRLH unit cell. The antenna structure is based on a composite right-left handed (CRLH) transmission line (TL) model used as a periodic structure. Because the lowest mode of operation is a LH mode, the propagation constant approaches negative infinity at the cut off frequency, and reduce its magnitude as frequency is increased. Making use of this phenomenon, an electrically large but physically small antenna can be developed. Figure 3 shows configuration of the proposed antenna, in this structure, port 1 is excited with input signal and port 2 is matched with  $20\Omega$  load impedance.

In this article, we using of MTM technology and the printed planar patches approach that results to foot print area reduction of the proposed antenna. Figure 3 shows configuration of the recommended antenna constructed of the four unit cells based on CRLH-TL structure that

Figure 4. Simulated reflection coefficient  $S_{11}$ .

was designed on a FR<sub>4</sub> substrate, with a dielectric constant of 4.6, a thickness of 0.8mm and Tan D=0.001. By means of the I-shaped gaps and spiral inductors with shorting via-hole connecting to ground plane, the series capacitance ( $C_L$ ) and shunt inductance ( $L_L$ ) can be easily

implemented in a squeeze fashion. In each unit cell, the series capacitance ( $C_L$ ) is developed by two the printed I-shaped gaps into radiation patches, and the shunt inductance ( $L_L$ ) is resulted from the spiral inductor shorted to the ground plane through the metallic via. The

structure possesses the right-handed parasitic effects that can be seen as shunt capacitance ( $C_R$ ) and series inductance ( $L_R$ ). The shunt capacitance is mostly come from the gap capacitance between the patch and the ground plane, and the unavoidable currents that flow on the patch establish series inductance, which indicates that these capacitance and inductance cannot be ignored. The proposed design procedure keeps the overall size of the unit cell compact while aims at reducing the ohmic loss to improve gain and radiation efficiency. Overall size of this antenna is  $0.16\lambda_0 \times 0.05\lambda_0 \times 0.006\lambda_0$  at the operating frequency  $f=2.2\text{GHz}$  where  $\lambda_0$  is the free space wavelength. With choosing smaller distance between printed I-shaped gaps edges, will be obtained wide bandwidth from 2.2 GHz to 3.05 GHz which corresponding to 850 MHz bandwidth. Furthermore, with appropriate selecting of the number unit cells ( $N$ ) constructing antenna structure and structural parameters, will be achieved good radiation performances. The gain and the efficiency of the proposed antenna are changed from 0.54dBi-4.1dBi and from 9.6%-68.86%, respectively, into frequency band 2.2 – 3.05 GHz, that shown good radiation characteristics. This antenna can support all cellular frequency bands from 2.2 GHz to 3.05 GHz, using single or multiple feed designs, which eliminates the need for antenna switches. These entire attributes make the proposed antenna based on CRLH-TL is well suitable for the wireless communication applications and mobile handsets.

## SIMULATION RESULTS AND DISCUSSION

The proposed MTM antenna is designed as a CRLH antenna where the substrate has dielectric constant  $\epsilon_r = 4.6$ , thickness  $h=0.8\text{mm}$  and  $\text{Tan } D=0.001$ . Squeeze broad-band recommended antenna is simulated by using ADS full-wave simulator. The simulated S11 parameter displayed in Figure 4 and simulated radiation gain patterns in 2.2, 2.5 and 3.05 GHz are plotted in Figure 5. The radiation patterns are unidirectional characteristics. The simulated gains at 2.2, 2.5, 3.05 GHz are 0.54, 2.63, and 4.1dBi, respectively. The simulated radiation efficiency is 9.6% at 2.2GHz, 43.18% at 2.5GHz, and 68.86% at 3.05 GHz.

The four unit cells squeeze broad-band antenna is designed from 2.2 GHz to 3.05 GHz and this antenna exhibit good matching between this frequency bands for  $20\Omega$  impedance port. The physical length, width and height of the suggested antenna are 22mm, 7mm and 0.8 mm ( $0.16\lambda_0 \times 0.05\lambda_0 \times 0.006\lambda_0$ ), respectively. The gain and the radiation efficiency of this antenna are varies from 0.54dBi to 4.1dBi and from 9.6% to 68.86%, respectively, into the frequency range 2.2 GHz-3.05 GHz.

## CONCLUSION

In this paper, we introduced a new concept of antenna size reduction with wide bandwidth accompanying enhancement gain based on a MTM design methodology. A practical squeeze, broad-band and high gain antenna with a simple feed structure and planar circuit integration possibilities has been demonstrated. Overall size of the recommended antenna is  $22\text{mm} \times 7\text{ mm} \times 0.8\text{ mm}$  or  $0.16\lambda_0 \times 0.05\lambda_0 \times 0.006\lambda_0$  at the operating frequency  $f=2.2\text{ GHz}$  where  $\lambda_0$  is free space wavelength. A return loss below -10dB from 2.2 GHz – 3.05 GHz was obtained which corresponding to 32% bandwidth. The peak gain and the maximum efficiency of the proposed antenna which occurs at  $f=3.05\text{ GHz}$ , are 4.1dBi and 68.86%, respectively. This antenna has the advantages of wide-band, compact size, high gain, unidirectional radiation patterns and simple implementation. The recommended antenna can be used for portable units such as mobile handsets and wireless communication applications.
